

# Lecture 04 AJAX

EGCI427

# JavaScript Execution Environment

---

- ▶ JavaScript executing in a browser
- ▶ The **Window object** represents the window displaying a document
  - ▶ All properties of the `window` object are visible to all scripts
  - ▶ Global variables are properties of the Window object
  - ▶ There can be more than one Window object
    - ▶ Global variables depend on which Window is the context
- ▶ The **Document object** represents the document displayed
  - ▶ The document property of Window
  - ▶ Property arrays for forms, links, anchors, ...
- ▶ The frames property of Window

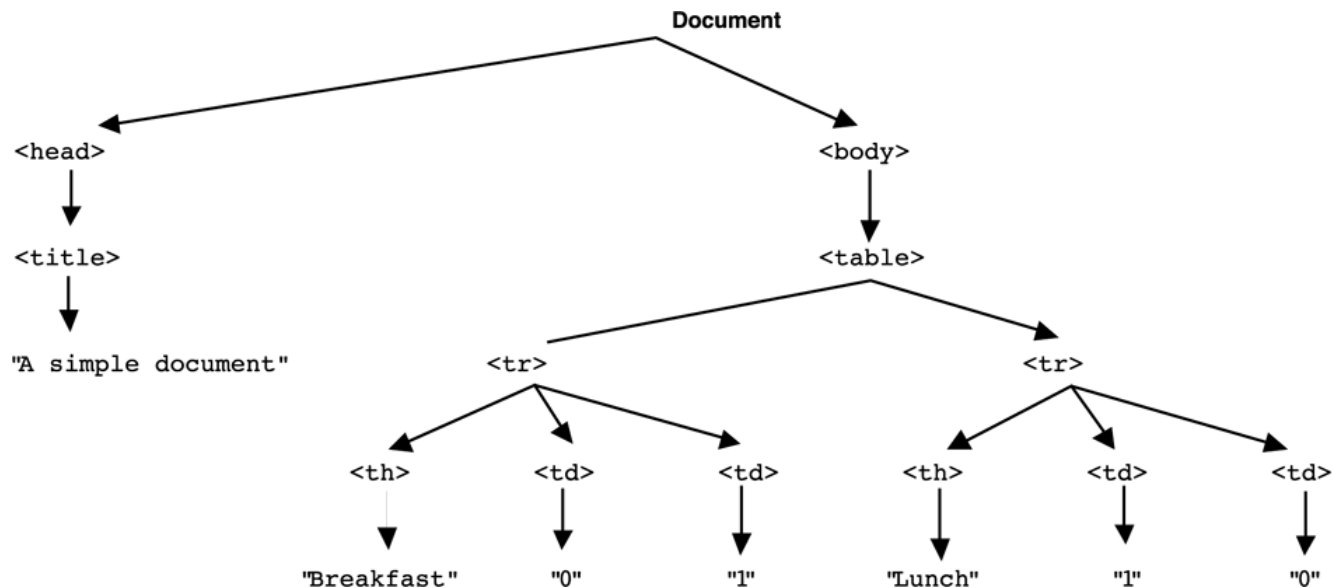

# Document Object Model (DOM)

---

- ▶ To provide a specification programs or scripts that deal with XHTML portable among various browser
- ▶ DOM Levels
  - ▶ DOM 0: informal, early browsers
  - ▶ DOM 1: XHTML/XML structure
  - ▶ DOM 2: event model, style interface, traversal
  - ▶ DOM 3: content model, validation
- ▶ DOM specifications describe an abstract model of a document
  - ▶ Application Programming Interface (API)
  - ▶ Interfaces describe methods and properties
  - ▶ The interfaces describe a tree structure
  - ▶ Different languages will bind the interfaces to specific implementations
    - ▶ The internal representation may not be tree-like
    - ▶ In JavaScript, data are represented as properties and operations as methods

# Example

```
<html xmlns="http://www.w3.org/19/xhtml">
<head><title>A simple document</title></head>
<body><table>
  <tr> <th>Breakfast</th>
    <td>0</td>
    <td>1</td>
  </tr>
  <tr> <th>Lunch</th>
    <td>1</td>
    <td>0</td>
  </tr>
</table> </body> </html>
```

# Example

---

- ▶ The HTML document on the previous slide is shown as a conceptual tree
- ▶ Nodes of the tree will be JavaScript objects
- ▶ Attributes of elements become named properties of element node objects
  - ▶ `<input type="text" name="address">`
  - ▶ The object representing this node will have two properties
    - ▶ type property will have value "text"
    - ▶ name property will have value "address"

# Element Access in JavaScript

---

- ▶ Elements in XHTML document correspond to objects in JavaScript
- ▶ Objects can be addressed in several ways:
  - ▶ `forms` and `elements` array defined in DOM 0
    - ▶ Individual elements are specified by index
    - ▶ The index may change when the form changes
  - ▶ Using the name attributes for form and form elements
    - ▶ A name on the form element causes validation problems
    - ▶ Names are required on form elements providing data to the server
  - ▶ Using `getElementById` with `id` attributes
    - ▶ `id` attribute value must be unique for an element

## Using forms array

---

- ▶ Consider this simple form:

```
<form action = "">  
    <input type = "button"    name =  
    "pushMe">  
</form>
```

- ▶ The input element can be referenced as  
`document.forms[0].element[0]`

# Using name Attributes

---

- ▶ All elements from the reference element up to, but not including, the body must have a name attribute
- ▶ This violates XHTML standards in some cases

- ▶ Example

```
<form name = "myForm"  action = ">  
    <input type = "button"  name = "pushMe">  
</form>
```

- ▶ Referencing the input

```
document.myForm.pushMe
```

- ▶ XHTML1.1 does not allow name attribute in the form element
  - ▶ Only validation problem but causes no difficulty for browsers

# Using id Attribute

---

- ▶ Set the id attribute of the input element

```
<form action = "">  
    <input type="button" id="turnItOn">  
</form>
```

- ▶ Then use getElementById

```
document.getElementById("turnItOn")
```

## Example of XMLHttp

# XMLHttp

---

- ▶ innerHTML
  - ▶ Update text based on user input
  - ▶ `document.getElementById('elementID').innerHTML = 'Text';`
- ▶ XMLHttpRequest
  - ▶ The XMLHttpRequest object is used to exchange data with a server behind the scenes
  - ▶ `xmlhttp=new XMLHttpRequest();`
- ▶ responseText
  - ▶ Returns the response data as a string
  - ▶ `xmlhttp.responseText`

# XMLHttpRequest

---

- ▶ `xmlhttp.readyState==4`
  - ▶ 0 Uninitialized - `open()` has not been called yet.
  - ▶ 4 Completed - Finished with all operations.
- ▶ `xmlhttp.status==200` is OK
- ▶ `open(method,url,async)`
  - ▶ Specifies the type of request, the URL, and if the request should be handled asynchronously or not.

*method*: the type of request: GET or POST

*url*: the location of the file on the server

*async*: true (asynchronous) or false (synchronous)

# XMLHttpRequest

---

- ▶ `send(string)`
  - ▶ Sends the request off to the server.

*string*: Only used for POST requests

- ▶ `xmlhttp.open("GET","Text",true);  
xmlhttp.send();`
